the report covers the validation of a soil stabilization index system which was developed earlier the index system was originated to aid military engineers in selecting the appropriate type and amount of soil stabilizer to use in pavement construction a

comprehensive review of literature in the soil stabilization field was used to initially develop the index system laboratory tests and discussions with experts in soil stabilization were used in the validation phase reported herein based on these tests and discussions several changes have been made to the initial index system although the original concept has not been altered the index system is entered with easily determined soil properties and flow charts are followed to arrive at the most suitable stabilizer subsystems containing appropriate tests are used to determine specific amounts of stabilizers use factors construction factors and environmental factors are also considered in the decision making process recommendations are included for additional verification studies of the index system

chemical stabilization of expansive soil has been practiced for quite a time now the use of lime cement stabilization as a traditional method has been well acknowledged understood and standard guidelines for practice have been developed however owing to certain demerits like high production and application cost environmental impact durability issues and most importantly incompatibility with high sulfate soil leading to excessive heaving and swell there is need to develop alternatives to these stabilizers non traditional stabilizers like ionic soil stabilizer have been used by manufacturers in the past and claimed to effectively reduce the swell shrink behavior of expansive soil undocumented results the absence of laboratory tests proprietary issues however have forced engineers to be reluctant about its use and accept it as suitable options to existing stabilizers this study has focused on meeting existing shortcomings of the ionic stabilizers by studying their effect on expansive soil both in the laboratory and field for this purpose an ionic soil stabilizer was selected from the available commercial products in the market the stabilizer was used to treat the expansive soil from carrollton texas the stabilizer was also used to treat a site in burleson texas the laboratory study focused on observing the effect of treatment on swell potential and strength of the soil at different application rates 1 150 and 1 300 volume of chemical to volume of water ratio and curing days and validating the results through micro analysis of the soil the laboratory tests include basic soil physical property and mechanical property tests such as atterberg limits test bar linear shrinkage test hydrometer test standard compaction test 1 d swell and unconfined compressive strength test soil mineralogy tests including cation exchange capacity and specific surface area were performed to determine soil mineralogy behaviors in addition micro tests such as scanning electron microscope sem imaging energy dispersive spectrometer tests were

perform to determine micro structure and elemental behavior of both treated and untreated soils further studies were conducted on the samples treated in the field as well with carrollton soil it is found the standard compaction curve is altered for the treated soil the optimum moisture content increases while the maximum dry density decreases for treated soil compacted at the optimum moisture content and maximum dry density of the treated soil more than 50 of swell reduction is observed and the ucs of the treated soil slightly decreases for burleson soil the standard compaction curve of the treated soil is similar to the one of untreated soil the ionic soil stabilizer is found to successfully reduce the swelling potential and pvr of the active zone of expansive soil generally extending up to 10 feet in field treatment in the field the soil is usually wetted to near saturation with the liquid stabilizer the application mass ratio which is the amount of stabilizer available for soil solids is relatively higher because of the treatment method used in the field the tests in the laboratory were done at the moisture content near to optimum in the light that improvements were observed with the burleson soil the stabilizer shows a potential in expansive soil stabilization there are some discrepancies in findings from the lab and the field which can be ruled out in the future with the development of techniques to closely simulate the field condition ineffectiveness of stabilizer on carrollton soil at given test conditions might be an indication that stabilizers work under certain specified conditions only and concludes that pre study of the suitability of stabilizer is essential nevertheless incorporating all the shortcomings in the current study ionic stabilizers can have a good potential in the future for stabilization of expansive soil
